Cyber Security: Trends and Observations

Key trends observed during the quarter

Major cybercrime forums taken down

A globally coordinated law enforcement effort has dismantled two of the world's largest dark web markets, <u>Alphabay</u>^{viii} and <u>Hansa</u>^{ix}. Criminals used these online, anonymous bazaars to advertise and sell illegal goods and services

such as drugs and weapons alongside user credentials and credit cards stolen in cybercrime campaigns. While the "takedowns" resulted in arrests of site administrators and some vendors, buyers and sellers appear to have migrated their business to alternative markets, where in many cases, they already had a strong reputation.

CHECKLIST

- Disrupting dark web activity requires meticulous, time-consuming and expensive law enforcement investigations. We assert with high confidence that irrespective of the resounding success of this operation, there will continue to be sufficient incentive for other markets to take their place as occurred after the widely heralded Silk Road takedown in 2013.
- Dark web markets are a good source of intelligence for cyber security teams to monitor where the wares stolen in credential phishing campaigns or other hacking campaigns are traded.
- It is probable that some cybercriminal groups will revert to forums with higher barrier to entry. While this slows the pace of campaigns in the short-term, it creates fresh challenges for law enforcement and intelligence analysts when attempting to monitor illegal activity.

Cybercriminals use renewal notice themes for bait

The CBA Cyber Security Centre has observed an increasing number of phishing campaigns that warn users that a service they (might) subscribe to requires renewal or some other form of action to avoid being deactivated. This technique - which relies on appealing to the user's sense of urgency - is used in a wide range of phishing lures. Over the last few quarters, we have seen lures that threaten revocation of everything from drivers' licenses to popular cloud services, bank accounts and subscription television services.

CHECKLIST

- Teach your staff the various 'triggers' used by cybercriminals to tempt a user to open an attachment or click on a hyperlink.
-) Phishing campaigns often rely on an urgent call-to-action. Consider working with your marketing teams to help them avoid sending communications to your customers that appeal to the same triggers, to ensure customers can discern between legitimate and illegitimate communications.

Poor configuration makes for leaky clouds

Pushing workloads into public clouds has provided development teams with far greater agility. From a security perspective, public clouds also allow for nonsecurity professionals to tap into security features

they might not have otherwise used. But conversely, public cloud dramatically increases an organisation's attack surface, leaving less room for error. Security researchers and malicious actors routinely find vulnerable assets using simple scans that target configuration errors. In the last guarter alone, a large number of organisations were found to have failed to secure storage volumes (S3 buckets) hosted in Amazon Web Services. including Dow Jonesxii, Groupizexiii, Time Warnerxiv, Verizonxv, Viacomxvi and an organisation that leaked the details of 9,000 US military veterans^{xvii}.

CHECKLIST

- While using public cloud frees developers and third party application service providers from infrastructure constraints, this mode of deployment often bypasses mature internal IT controls that ordinarily would check for configuration errors. Security teams should work with these teams to develop repeatable architecture patterns for deploying systems to the cloud securely. AWS offers reference material for producing architecture patterns^{xviii}.
- Deducate developers and partners on the distinction between configuration settings that allow authenticated users of your service to access a data store, versus those that allow all authenticated users of Amazon Web Services (over a million users) to access it. AWS infrastructure can be readily monitored and free tools are available to check services are configured correctlyxix.
- Consider broadening the scope of your assurance practices. Many organisations now complement tightly-scoped penetration testing with objective-based testing by "red teams", who are empowered to proactively search for data left unsecured online, including by third parties. Australian Daniel Grzelak has developed free tools for taking a red team approach to services hosted on AWS.

Cyber Security:

Trends and Observations

Software supply chains targeted for mass compromise

Aggressive, well-resourced cyber-attacks continue to target private organisations in contested territories, raising further concern that some nation-state aligned actors view industry as a legitimate target during periods of increased geopolitical instability. The [Not] Petya network worm was initially propagated^{xxi} by the compromise of a server^{xxii} that distributes software updates to customers of Ukrainian accounting software vendor M.E.Docs. The compromised update resulted in immediate disruption to over 2000 Ukrainian firms and multinationals that do business in the region and ultimately led to billions of dollars worth of damage to the global economy. In August 2017, a similar backdoor was detected in a software update distributed by

NetSarang, a South Korean provider of remote administration software usedxxiii at large firms around the globe.

CHECKLIST

- > Establish a governance program to identify and manage risks posed by your software supply chain.
- > Where practical, evaluate the impact of software updates on test systems, prior to a broader rollout across production systems.
- > The US National Institute of Standards and Technology has updated its overarching frameworkxxv to include more advice on managing third party cyber security risk.
- > Strive to work with well-resourced suppliers that have demonstrated an ability to respond to cyber security incidents.

Breaches stem from flaws in web frameworks

Most modern web and mobile applications inherit their key features from web application frameworks and the software libraries and protocols they include. They are the scaffolding that enables rapid development and deployment of apps - they are typically freely available, broadly deployed and maintained by a community of users and enthusiasts. They are also a juicy target for attackers looking to achieve scale. Security vulnerabilities found in the Apache Struts framework and numerous JavaScript frameworks^{xxvi} have demonstrated broad-scale impacts on hundreds of organisations at a time. As a case in point, attackers stole 145.5 million sensitive customer records from

US credit monitor Equifax after it failed to patch a vulnerability in Apache Struts in a timely manner*xvii. The breach forced the early retirement of the company's CIO, CSO and CFO.xxviii

CHECKLIST

- > Monitor closely for disclosure of vulnerabilities in the web application frameworks used by your organisation. Patch or update expediently.
- Your application security program should ideally be testing and endorsing software libraries. protocols and other components of web application frameworks to provide developers greater confidence over which versions to use.
- Smaller firms might assess a web application framework on how quickly and effectively the community has historically responded to vulnerability disclosures with patches.

Expired domains and browser plug-ins hijacked to host malware

Attackers continue to find creative places to host malware that circumvent detective security controls. In recent months, security researchers have discovered malware hosted on legitimate domains that organisations have neglected to renew, or have observed attackers hijacking abandoned or unsupported web browser extensions, CMS plugins and themes. More audacious attackers have compromised the developers of popular browser extensions in campaigns that impact millions of users, albeit

for a shorter time. These domains and extensions are more likely to be trusted (and less likely to be blacklisted) by automated security tools, providing attackers a ready-made number of victims to infect and longer window of time to do

CHECKLIST

- Organisations with low thresholds for risk must decide whether certain types of sites or applications are adequately resourced from a security perspective to remain resilient. Some organisations, for example, choose to block sites built using the WordPress CMS by default - owing to a litany of unsupported plug-ins used in these sites - and only whitelist them on request. Check your logs: what impact would such a decision have on legitimate access of sites using these technologies?
- > Equally, software development teams must think carefully about how to manage third party resources that load onto their web sites. What risks might your organisation face if these third party services were compromised? Do the providers of these resources have adequate security capability, or are they at least popular enough that developers have incentive to continue to support and update them?

Social engineering - coupled with access to your inbox - presents attackers with many paths to profit.

o a profit-motivated cybercriminal, access to your email inbox can be as valuable as your bank account. That sounds counterintuitive – until you compare the difficulties an attacker faces in trying to personally extract money directly from your bank account, versus convincing you or the people that you interact with to make a payment for them.

Over the last nine months, there has been a steady rise in the number of businesses that have made payments to attackers after a compromise of their email account, or that of an entity they do business with.

Access to a victim's inbox isn't the only way an attacker can trick victims into make payments, as discussed in previous guidance on 'whaling'xxxi and other forms of Email Payment Fraud'xxxi. Organisations continue to be duped into making payments in response to emails that impersonate a party to the transaction, either via spoofing of a legitimate domain, or registration of similar domains and webmail addresses. Education has slowed the growth of these campaigns, but they still responsible for a large volume of fraud.

As organisations move their email into cloudhosted systems for the first time, many neglect to configure appropriate security controls. Cybercriminals have seized on this new opportunity - and the range and sophistication of scams that involve unauthorised access to email accounts has risen dramatically.

Leading indicators

One in four fraud losses over the past six months involved the compromise of a cloud-based email account.

The majority were Microsoft Office 365 cloud accounts, or consumer-grade Microsoft email accounts (Hotmail etc.) used by tradesmen and other small businesses. This reflects Microsoft's dominance in the enterprise market. Well over 100 million active users of Office 365 log in each month, and most of these users work for businesses in the developed world. A further 30 million log-in to Microsoft's consumer-grade email services each month – and a subset of these are small businesses that haven't migrated to Office 365. Microsoft's main competitor in cloud-based productivity, Google's G-Suite, has struggled to attract 10% of the business market.

Microsoft is subsequently an ideal brand for attackers to imitate. Over the last four weeks, no single brand was impersonated more often in credential phishing campaigns (fake web sites set up to steal user credentials) than Microsoft.

Image 1: Generic Microsoft Office365 phishing page

On some of the abuse reporting channels we monitor, twice as many Office365 and Outlook Web Access phishing pages were stood up than those imitating Apple services (iCloud, iTunes etc.), and five times as many as phishing sites that mimic Google services.

Microsoft has reported a 300 percent increase in attacks on user accounts in the first quarter of 2017 compared to the corresponding quarter in 2016, while the number of account signins attempted from malicious IP addresses increased by 44 percent over the same period.

The scam(s)

There are two primary ways for profit-motivated attackers to access cloud email accounts.

The first is "credential stuffing", in which the attacker attempts to use credentials (usernames and passwords) stolen in attacks on other online

By the Numbers

Top 3 events that lead to fraud losses:

- 1. 'Spoofing' an email address to request payment
- 2. Unauthorised access to an email inbox
- **3.** Unauthorised access to accounting software or bank account

One in four

losses involved the compromise of a cloud-based email account.

10:9

Scammers continue to imitate suppliers or other payment beneficiaries slightly more often than CFOs and Directors.

service providers, under the expectation that people often re-use passwords for multiple services.

The second is by acquiring credentials stolen in phishing campaigns. Perpetrators of phishing campaigns create web sites that mimic the branding of legitimate log-in pages (see Image 1), and send spam runs that try to convince legitimate users of those services to enter their credentials. Credentials harvested in phishing runs are often sold to other criminals whose intent is to commit fraud. Numerous phishing

66 Numerous phishing web sites are set up to imitate Microsoft services on a daily basis 99

SEE CERT NZ ADVISORY:

Office 365 phishing and credential harvesting campaign, September 18, 2017

https://www.cert.govt.nz/businesses-and-individuals/recent-threats/office-365-phishing-and-credential-harvesting-campaign

web sites are set up to imitate Microsoft services – as well as banks and other popular online service providers – on a daily basis. They are typically blacklisted or forced offline within hours, but not before a number of users have given away their credentials.

The criminals that run Business Email Compromise scams typically use these stolen credentials to log in and search an inbox for evidence of invoices, purchase orders or other documents and messages that relate to processing of large value payments.

The attacker's aim is (usually) to be the 'man

Who is attacking us?

Research by SecureWorks and Trend Micro note that Business Email Compromise - in which attackers hack an email system as a precursor to tampering with payments - is a mature industry in West African countries like Nigeria, where employment prospects are otherwise slim. These criminal networks consist largely of graduates from simple social engineering scams. These actors have grown more patient, and are prepared to invest in malware (such as remote access troians) or in buying access to stolen user credentials from phishing campaigns. While perpetrators are by no means limited to West Africa - indicators from many of the attacks we've seen (even those that originate in Asia) are very similar to practices West African cybercriminal groups are renowned for.

What payments are at risk?

Any payment arranged over email:

- Invoices between suppliers, especially among tradesman, engineering and construction firms, manufacturing and distribution.
- > Payments to staff (payroll).
-) Beneficiaries of property sales (trust accounts) or payment of rent.
- Beneficiaries from the sale of expensive items (vehicles etc.)
- > Beneficiaries from settlement of a will.
- > Beneficiaries from tax refunds.

in the middle' between buyers and sellers who establish the details of a transaction over email. Attackers will intercept and edit existing invoices to replace the bank account details listed for payment, or email customers from a compromised account advising of new account details for future payments. If the account they hack into belongs to a person with purchasing authority, they might simply demand a subordinate make a payment on their behalf.

The attackers have proven to be very patient. They refer to these scams as the "long con" - and will monitor an inbox for some time while waiting for a large payout opportunity. Often the attackers set up mail forwarding rules to automatically send messages to the webmail accounts they log into more regularly.

Strategies for protecting your cloud email

The most critical defence against business email compromise is multi-factor authentication (MFA).

Multi-factor authentication challenges users to authenticate (prove their identity) in more than one channel before they can access a system. They usually must combine something they know (a username and secret password on a web interface, for example) via one channel, and confirm with something they have (such as a random set of characters sent to their mobile device, for example) in another.

Microsoft and Google both offer multi-factor authentication 'out-of-the-box' for business customers. Provisioning to users is straightforward, as is choosing <u>what second factor is most appropriate</u> and when users should be presented with a multi-factor challenge.

Instructions for setting up multi-factor authentication

- > For Microsoft Office 365 administrators xxxiv
- > For Google G-Suite administrators xxxv

The typical argument against MFA is that it inconveniences users. Both of the major cloud email service providers offer ways to reduce this friction. Google G-Suite users can check a box to "remember verification for the computer", which sets up an authentication cookie between the user's browser and their G-Suite account. The cookie expires (and an MFA challenge is presented to the user) every 30 days. Office 365 users can set up passwords for bypassing the second-factor on mobile devices, for example, but keep it in place for log-in over the web.

A range of other suggested security controls are outlined on the following page.

66 Multi-factor authentication limits attackers from accessing a service using only a stolen username and password 99

Strategies for protecting your cloud email

1: Theft of Credentials				
METHOD OF ATTACK	ESSENTIAL DEFENCE	ADVANCED DEFENCE		
Attackers acquire user credentials stolen in phishing campaigns.	Multi-factor authentication limits attackers from accessing a service using only a stolen username and password. Multiple (Managers halo ways)	Consider deploying multi-factor authentication.		
'Credential stuffing' - attacker tries usernames and passwords stolen in other data breaches to log in to your email account.	Password Wallets/Managers help users create unique and complex passwords for every service they use. Finder password policies that lock a user out for a period of time after a number of failed attempts.			
Attackers infect a user's device with malware to steal credentials.	1. Set web browsers to automatically update and keep operating systems patched. 2. Ensure users operate as the least privileged user (not admin/root). 3. Filter web traffic (via internet security software/antivirus.) 4. Implement security awareness programs.	Consider deploying multi-factor authentication .		

2: Unauthorised access to email account				
METHOD OF ATTACK	ESSENTIAL DEFENCE	ADVANCED DEFENCE		
Attacker is able to log-in using stolen credentials on an account that is <u>not</u> protected by multi-factor authentication.	G-Suite. While their approaches vary, these rules allow an administrator to set conditions of access according to whether the user is	Microsoft offers additional rules-based and machine learning algorithms to detect and block anomalous log-in behaviour as a premium (paid) service. Google uses a range of machine learning-based detection into its standard G-Suite offering.		
Attacker is able to log-in using stolen credentials of an administrator's account that is not protected by multifactor authentication.	whether they are on managed or unmanaged devices or according to a set of whitelisted IPs addresses, for example. For any combination of these scenarios, rules can be set to accept, deny or force a multi-factor challenge for access to the inbox.	Limit the number of accounts that require 'global' or 'super user' administrative access. Microsoft offers a premium (paid) privileged access management solution.		

3: Reconnaissance of the inbox				
METHOD OF ATTACK	ESSENTIAL DEFENCE	ADVANCED DEFENCE		
Attacker sets mail forwarding rules to send mail to their own account.	Consider <u>conditional formatting</u> <u>mechanisms</u> that distinguish (through colours or alerts) when email is being sent to or received from internal versus external domains.	Microsoft offers additional rules-based and machine learning algorithms to detect and block anomalous mail forwarding behaviour as a premium (paid) service.		
	If users report any <u>strange behaviour in their inbox</u> , check if any mail forwarding rules have been applied. While these can usually be seen in the user interface of Office 365, administrators should also check under the hood using <u>PowerShell commands</u> .			

4: Fraudulent request for payment				
METHOD OF ATTACK	ESSENTIAL DEFENCE	ADVANCED DEFENCE		
Whaling attack (attacker impersonates staff with purchasing authority and requests a payment)	Ensure your payments authorisation process "assumes compromise": 1. Make use of multiple authorisers for payments and enforce strict separation of duties for payments.			
Attacker impersonates a supplier (or other party to a transaction) and requests a change of beneficiary details or submits a new invoice.	Require large payments or change of beneficiary details to be verified via additional checks in multiple channels. No payment should be authorised on the basis of emails from a single account. Education your treasury and accounts teams in how to recognise Email Payment Fraud.			

5: Fraudulent payment is made

- Contact the Fast Business helpdesk (0800 225 527) and your relationship manager immediately.
- Report the matter to the Police.
- Use the following guides to triage of compromised accounts provided by <u>Google</u>xxxvi and <u>Microsoft</u>xxxvii.

A beginner's guide to quantifying cyber risk

Establishing the foundations of a cyber security program

like floods or power outages provide the insurance industry the data required to model the likelihood and impact of future events within such a degree of accuracy, they can base a business on it.

Threats to cyber security, by contrast, are relatively new phenomena. In our two decades connected to the internet, the threat landscape has been anything but predictable. As the volume of vulnerabilities in the technologies we use amass, the capability of threat actors evolves and the number of high profile security incidents ensues, uncertainty abounds. The under-resourced CISO measures risk to cyber security with a wet finger in the air.

As boards of organisations grow more engaged on cyber security, CISOs should anticipate demands for a more rigorous approach to quantifying risk.

While there is insufficient public data available to accurately predict low probability, high impact events, there are numerous frameworks, models and thought exercises that can help an organisation approximate cyber risk, and over time, refine it into something resembling a science.

Directors, CEOs and CFOs can play an important role in the process.

Key concepts

Before we begin, it's best to agree on some high level concepts. **Risk** is a measure of potential loss if an event were to occur. 'Cyber risks' are a subset of organisational risks that are caused by a cyber security threat. A cyber security **threat** is an event with the potential to cause harm to an organisation's information assets by circumventing confidentiality (via unauthorised access and/ or disclosure), integrity (via modification of data) or availability (via destruction or denial-of-service).

In cyber security, we usually talk of **vulnerability** to describe specific weaknesses in systems. But when quantifying risk, we are referring more generally to an organisation's 'susceptibility to a threat'.

Security **controls** are countermeasures to a threat that attempt to prevent, detect or recover from a cyber security event. When we **remediate** an identified risk, we're reducing its impact to near zero, while when we **mitigate** a risk we're accepting that there will be a residual risk and that the best we can do is to monitor and respond to events to minimise their impact.

How do we get started?

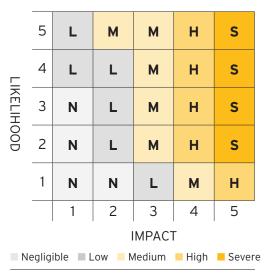

First, you need to understand the threat. Why would various actors - whether malicious or otherwise, inside or outside your network - seek to gain unauthorised access to your data or disrupt your systems? You'll need to get a measure of the threat landscape to understand what threats have targeted or are likely to target your organisation. Signals is a good place to start!

Next, the board and executive need to define and endorse an acceptable level of risk.

Most organisations use a risk matrix, with likelihood of an event on one axis (expressed as probability or %), and impact on the other (expressed on a scale of inconsequential or negligible up to severe or critical).

Determining an acceptable level of risk is often best arrived at by talking about what's unacceptable. For how long would the organisation accept an inability to serve customers online? How much money would the organisation be prepared to lose each year to fraud events? Think about risks to customers, to staff, to brand or reputation. Answering these questions helps to define your 'risk appetite statement' - an expression of where in that matrix would you feel comfortable to sit, knowing that not all risks can be remediated.

A generic risk matrix

Once you quantify your risks, you'll be able to visualise where you are now and where you need to get to.

An invaluable pre-requisite to the exercise is a living register of the organisation's IT and data assets. This might be a hard ask in large and complex organisations, but it's important to at least get a handle on what the 'crown jewels' are. Organisations that do this the best tend to have benefited from strong executive support to get everyone on board with how critical this register is.

Deep Dive: A beginner's guide to quantifying cyber risk

66 Cyber security professionals can rattle off an inexhaustible number of ways an organisation can be attacked, but risk analysis requires structure 99

With these in hand, the security team have what they need to start threat modelling.

Modelling cyber risk

There are numerous theories on how best to quantify cyber security risk. Most follow a similar process and are distinguished by the level of mathematical detail required to reach conclusions. (The authors of the most scientifically rigorous model - Factor Analysis of Information Risk (FAIR)xxxviii, for example, claim the standard for risk metrics originally established by NIST is too loosely defined. But they'd also concede that their work inherits its foundations from it.)

Just about every model attempts to calculate the inherent risk (a measure of risk before compensating controls) for a range of threat scenarios, using something like the following model: Cyber risk = threat (#) x vulnerability (%) x impact (\$).

As the table below demonstrates, for any given threat scenario, you need to assess (or predict) how often you should expect to encounter the threat scenario over a given period of time, what percentage of your systems would be vulnerable if the threat were to play out, and an expected loss your organisation would face if the threat were to play out.

Cyber risk per threat scenario

	Threat	Vulnerability	Impact
Expressed as	A number	A percentage	A cost
Question:	How often have you or do you expect to encounter this threat scenario over a given period of time?	What percentage of your systems or data would be vulnerable to the threat scenario?	What would be the expected loss your organisation would face if this threat scenario were to play out?
Example:	The organisation has detected x malware campaigns each year that combine that spread via SMBv1 and deliver a ransomware payload.	What percentage of systems are not yet patched against known vulnerabilities in SMBv1?	What is the estimated cost of an infection, taking into account the ability of the network worm to spread through vulnerable systems, the cost of rebuilding systems and potentially the costs of managing reputational damage or shareholder value if the infection were to be known to the public?

Data quality

Cyber security professionals can rattle off an inexhaustible number of ways an organisation can be attacked, but risk analysis requires some structure. You can group cyber risks by asset, for example, or by whether the threat scenario would impact the confidentiality, integrity or availability of data. You might also classify by actor group (insider, third party partner, external party). Every <u>risk framework</u> tends to include its own taxonomy to follow, and all aim to consider a broad coverage of threats.

As you think through threat scenarios, you'll undoubtedly stumble onto those for which you don't have the required data to measure. This can be problematic if you are yet to implement an incident response or vulnerability management capability – both of which provide strong metrics to compare with.

So to some degree, the initial assessment in an organisation thinking about cyber security for the first time might need to include desktop research. MITRE's CVE database provides a global view of vulnerability data, the Californian State register of data breaches is the longest running register of breach events, and Verizon's annual data breach investigations report also has a long history.

(NB: always seek to validate data provided by parties that have skin in the game - such as vendors of security software - by correlating with independent, trusted sources.)

The more meticulous you are, the better. But you will have to accept, at some point, that until you stand up some semblance of security capability, your numbers are going to include approximations. Even the authors of the FAIR model, who believe that everything can be measured, concede that the main aim of the exercise is to "reduce management's uncertainty about risk" rather than calculate it with absolute accuracy.

There are other reasons this game of mental gymnastics is valuable. Your initial aim might be to quantify your total exposure to cyber risk. But it's an important baseline for other reasons. In an environment with an unknowable number of emerging threats, quantifying cyber risk can also provide a way of prioritising investment in cyber security programs - a subject that demands its own deep dive.

Tracking your progress

The exercise we've described should spare directors and business leaders from the gory detail of every security threat to the

Deep Dive: A beginner's guide to quantifying cyber risk

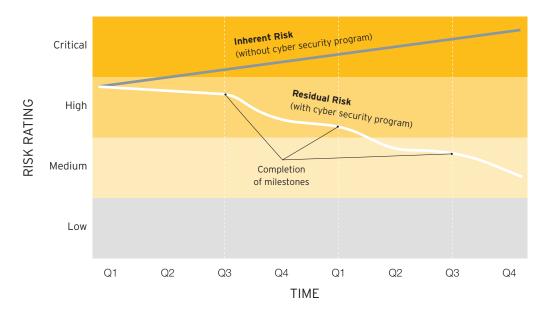

organisation, but nonetheless deliver a reasonably consistent, "10,000 foot view" of aggregate risk. It may be beneficial to illustrate what you've measured - preferably in a way that pinpoints where you've started, what your total inherent risk would have looked like without your security programs in place, and a decline in your residual risk as new controls or programs are delivered. This is something you should return to repeatedly, adjusting

for changes in scope or shifts in the threat landscape.

You should also assume that the quality of data you're feeding into your model will improve as you mature your security capability. We'll dive deeper into this in a future edition of Signals.

Brett Winterford contributed to this report.

Buying down risk

2017 Nov 20 Wellington

NZITF (New Zealand Internet Task Force) Annual Conference

The New Zealand Internet Task Force (NZITF) is a non-profit with the mission of improving the cyber security posture of New Zealand. It is a forum based on mutual trust for debate, networking, information sharing, and collaboration on matters relating to the cyber security of New Zealand.

2017 Nov Wellington, Te Papa Museum

The goal is to expand the spectrum of knowledge and understanding through conversation by creating opportunities for individuals to both present and participate in an intimate atmosphere that encourages discussion and collaboration. It is an intense event with discussions, demos, and interaction from participants. It is where conversations on the next big thing are happening.

2017 Nov 27

Cyber Smart Week

CERT NZ and Connect Smart are proud to present Cyber Smart Week - New Zealand's cyber security awareness week.

B

Better Practice:

The latest advice your technology team should consider when setting security policies:

How an organisation deals with vulnerability disclosures is an important signal to the public about security maturity.

Prepare for ransomware

A team at NIST and MITRE have collectively drawn up a <u>comprehensive guide</u> to recovering from ransomware and other destructive malware attacks^{xiii}. The top-level advice: segregate your network and remove unnecessary administrative access to systems to prevent an infection spreading, monitor log data (and consider file integrity monitoring) for improved detection and triage, and practice backup and recovery.

The end of Flash

Vulnerabilities discovered in Adobe's Flash media player - once a de facto standard for multimedia on the web - have been exploited by numerous APT and cybercrime campaigns. Multiple operating systems - starting with Apple's iOS in 2010, and more recently web browsers, have subsequently stopped supporting Flash content. Adobe has finally conceded that Flash has no future and announced that it will <u>no longer be supported</u> by Adobe by the end of 2020xliii. It is highly probable that most use of Flash will be phased out much sooner.

Find the bugs first...

One of the most critical components of a cyber security capability is establishing an assurance program where applications and/or infrastructure are tested by professional "white hat" hackers. The UK National Cyber Security Centre now provides https://doi.org/high-level.advice on how your organisation can build the foundations of an assurance function – a penetration testing team.**

... Before somebody else does

Even organisations with strong assurance practices can be surprised by vulnerabilities discovered in their internet-facing systems by external researchers. The way in which an organisation deals with these reports is an important signal to the public about your security maturity. One of the world's best authorities on 'coordinated vulnerability disclosure' is the Computer Emergency Response Team (CERT) at Carnegie Mellon University, who have published a <u>very comprehensive guide</u> for both security researchers and defensive teams.

Know your adversary

Imagine if there was one wiki where all the known TTPs (tactics, techniques and procedures) could be summarised to make your threat modelling that little bit easier. BAM! The good people at MITRE have published one. It's called <u>ATT&CK</u>xlvi and it looks to be a well-thought out product.

It's not too late to be infected with [Not]Petya

The news headlines may have slowed, but we're still seeing indicators consistent with the [Not]Petya network worm light up every so often. It's not too late to read <u>US CERT's revised advicexivity</u> on how to prevent and remediate these infections.

Shape a NICEr security team

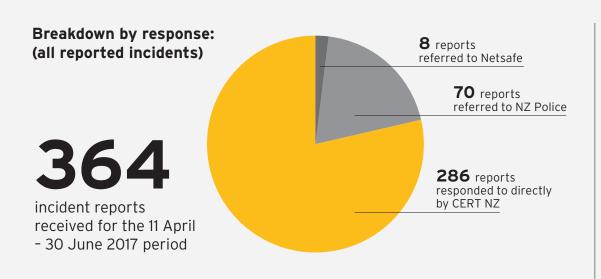

What are the typical roles and responsibilities of a cyber security team? Cyber security operations and US tertiary education providers have for the last three years used the NICE cybersecurity workforce framework published by NIST to answer this question. In August 2017, NIST <u>updated the framework</u>*Iviii to reflect shifts in workforce demand.

CERT NZ's cyber security incident statistics from around the country
